LIST OF EXPERIMENTS

1. Use commands like traceroute, tcpdump, ifconfig, netstat, and nslookup. Utilizing a network protocol analyzer, record ping and traceroute PDUs and investigate them.

a. The tcpdump command examines TCP/IP packets sent across networks when two end systems are connected via a specified interface.

b. Consider that the laboratory has 60 machines connected to the internet, use netstat commands to monitor incoming and outgoing network connections, view routing tables, interface statistics, etc.

c. The IP address has information about how to reach a specific host, especially outside the LAN. An IP address is a 32-bit unique address having an address space of 232. Use ipconfig command to identify the IP address of a node in a network and tracert command to show connection details about the path that a packet takes from the computer or device you're on to whatever destination you specify.

2. You are assigned to configure the facility, which has ten computers. Now your job is to configure the network cable in the facility, which has two types of cables (a) cross-through cable and (b) straight-through cable.
   a. First, use the color coding and understand how the cables are jacked with RJ45. You are assigned to crimp the two sides of the cable with a cross-through cable. Observer, understand, and experiment with the crimping process.
   b. Second, use the color coding and understand how the cables are jacked with RJ45. You are assigned to crimp the two sides of the cable with different network end devices through the cable. Observer, understand, and experiment with the crimping process.
3. PC1(192.168.1.2) and PC2 (192.168.1.3) are to be configured to communicate with each other. You are about to use the switch as an intermediate device in this experiment. Configure Cisco 2960 switch with the two PCs mentioned above. Experiment and observe that the data transfer between two computers is reliable.
4. Two computers, PC1(192.168.1.2) and PC2 (192.168.2.3), from different networks must be configured to communicate with each other. In this experiment, you will use the router as an intermediate device. Configure Cisco 1841 ISR router with the two PCs mentioned above. Experiment and observe that the data transfers between two computers are reliable.

Dr. R. DEVI PRIYA, B.E., M.E., Ph.D
Professor & Head
Department of Computer Science and Engineering
KPR Institute of Engineering and Technology

5. The communication between LAN and WAN is to be configured through Network Address Translation (NAT) as a border router. Create a NAT topology with three routers, RT1, RT2, and RT3. Configure static NAT on Router 2(RT2) while Router RT1 is configured in LAN and RT3 is configured in WAN. Use the following IP address to configure the router
   Router 1 (RT1) IP address: 192.168.1.2 (local)
   Router 3 (RT3) IP address: 110.120.1.2 (local)
   Router 2 (RT2) IP address: 110.120.1.2 (global)
   After configuring the IP address, check the packet situation by opening debug with the "debug ip icmp" command. Observe and under the displayed.
   Now configure the NAT using packet tracer (use the manual to configure). Experiment with different configuration scenarios and check the packet situation between LAN and WAN.
6. The routing information protocol (RIP) is used in this experiment to understand the hop count as a routing metric to find the most suitable route between the source and destination network. Configure RIP across the network and set up end devices to communicate on the network by enabling and verifying RIP commands. Create a routing table consisting of the following parameters: device name, IP address, subnet mask, and default gateway. Assign RIP route to a particular router and verify the network by pinging the IP address of any PC.
7. The client-server communication is studied in this experiment using socket programming to understand the UDP protocol. The server program and client program is executed separately. Initially, the UDP socket is created at the server and client sides. The binding is carried with the server address. Ensure that the client initiates the communication. Check the response of the client from the server side. Process the datagram packet and send a reply to the client. Observer that the data transfer between Client and Server occurred.
8. The client-server communication is studied in this experiment using socket programming to understand the TCP protocol. The server program and client program are executed separately. Initially, the TCP socket is created on the server and client sides. The binding is carried with the server address. Ensure that the client initiates the communication. Check the response of the client from the server side. Process the packet and send a reply to the client. Observer and ensure that the data transfers between Client and Server are reliable.
9. The active and passive File Transfer Protocol is studied in this experiment to understand the basic communication architecture between client and server. The server and client program with the following IP address should be used
   Server: 127.0.0.1
   Client: 192.168.x.x
   Active FTP: Write the client and server program and ensure that client initiates a session via a command channel request and the server creates a data connection back to the client and begins transferring data. Use Wireshark to snip the data packets. Experiment and observer the above by enabling and disabling the local firewall.
   Passive FTP: Write the client and server program and ensure that server uses the command channel to send the client information to open the data channel and ensure that the transfer has
